MSc in Computer Science 2017-18

Project Dissertation

Project Dissertation title: Reflectance Transformation Imaging

Term and year of submission: Trinity Term 2018

Candidate Name: Johannes Bernhard Goslar

Title of Degree the dissertation is being submitted under: MSc in Computer Science

Abstract

Vivamus vehicula leo a justo. Quisque nec augue. Morbi mauris wisi, aliquet vitae, dignissim eget, sollicitudin molestie, ligula. In dictum enim sit amet risus. Curabitur vitae velit eu diam rhoncus hendrerit. Vivamus ut elit. Praesent mattis ipsum quis turpis. Curabitur rhoncus neque eu dui. Etiam vitae magna. Nam ullamcorper. Praesent interdum bibendum magna. Quisque auctor aliquam dolor. Morbi eu lorem et est porttitor fermentum. Nunc egestas arcu at tortor varius viverra. Fusce eu nulla ut nulla interdum consectetur. Vestibulum gravida. Morbi mattis libero sed est.

4 Requirements and Design

4.1 Requirements

Distilling these, I arrived at the following functional requirements, which are logically grouped into fileformat/support and viewer.

For the fileformat:

1. Support for the PTM[4] fileformat.
2. Support for the RTI[5] fileformat.
3. Conversion of the formats above into a unified format.
4. Extended metadata support.
5. Support for high resolutions.
6. Support for higher bitdepths per pixel than the 8 of PTM/RTI.
7. Easy exchange between multiple researchers.

For the viewer component:

8. Runnable on all major operating systems and/or web browsers.
9. Lightning Controls.
10. Quick navigation functionality.
11. Annotations.
12. Overlays.

Continuing the enumeration of the functional requirements, following non-functional requirements were extracted:

13. Free Software, the implementation should be available for everyone to change and distribute.
14. Easy on-boarding of new developers, either scientists in a research context or students in an education context.
15. Good developer experience.
16. Adequate performance, at least keeping up with current implementations.
17. Easy installation for researchers.

18. “Web”-Based.
19. Instant reactivity.
20. Reasonable file sizes for instant transfer/viewing.
21. Preservable software and BTF files.

5 Implementation

5.1 Overview

This section explains the current implementation of the developed tool set, it is primarily targeted to fulfill the dissertation's requirements. But is also aiming to be helpful for users wanting to understand the underlying systems and prepare them for potentially joining the development effort. Abridged code extracts are used as of their state for thesis submission, while the main principles will hold, later readers are asked to please consult the actual source code if any discrepancies arise or reexport the document. First the main libraries are shortly explained in their relevance to the program, second the largely abstract plugin architecture is shown, third the main plugins are presented and last the delivery processes to the end users are described.

All implementation files are contained and delivered inside a single git repository, which is freely available online: <https://github.com/ksjogo/oxrti>. All following file paths are relative to that repository's root. All future development will be immediately available there and the current compiled software version is always fed automatically from it into the hosted version at <https://oxrtimaster.azurewebsites.net/api/azurestatic>.

5.2 Libraries

TypeScript

The official header line of TypeScript show some points why it was picked for this project: "TypeScript is a typed superset of JavaScript that compiles to plain JavaScript. Any browser. Any host. Any OS. Open source." [25] Which fits requirements 13, 8. Whereas plain JavaScript would have allowed slightly easier initial on-boarding and maybe easier immediate code

‘hacks’, TypeScript will provide better stability in the long run and a quite improved developer experience (requirement 15) in the long run. With the full typed hook system (compare section 5.4) it ensures that a compiled plugin will not have runtime type problems, reducing the amount of switching between code editor and the running software. The whole project is setup in a way to fully embrace editor tooling, Visual Studio Code[26] and Emacs[11] are the ‘officially’ tested editors of the project. Code is recommended as it will support all developer features out of the box. The installation of the tslint[23] plugin[24] is recommended to keep a consistent code style, which is configured within the *tslint.json* file. Most importantly TypeScript adds type declarations (and inference) to JavaScript, e.g.:

```
1 const thing = function (times: number, other: (index: number)
  ↵ => boolean) { ... }
```

would define *thing* as a function, taking a numbers as first argument and another function (taking a number as first parameter and returning a boolean) as second argument. The other most used TypeScript features inside the codebase are Classes[2], Decorators[6] and Generics[9], which will be discussed at their first appearance inside the code samples.

React

The two main points on React’s official website are “Declarative” and “Component Based”[18], which is best shown by an extended example from their website, which exemplifies multiple patterns found through the oxrti implementation. The most important concept is the jump from having a stateful HTML document, which the JavaScript code is manipulating directly, e.g.:

```
1 document.getElementById('gsr').innerHTML=<p>You shouldn't do
  ↵ this</p>"
```

Which is diametric to requirements 14 and 15 as it would require developers to manually keep track of all data cross-references (e.g. the pan values having to automatically adapt to the current zoom level). A declarative approach instead allows much better and easier implemented reactivity and better performance (requirements 16 and 19) as the necessary changes can be track and components be updated selectively.

```
1 // a class represents a single component
2 class Timer extends React.Component {
```

```
3 // the parent component can pass on props to its
4 constructor(props) {
5     super(props);
6     this.state = { seconds: 0 };
7 }
8
9 tick() {
10    // the state is updated and the component is
11    // automatically rerendered
12    this.setState(prevState => ({
13        seconds: prevState.seconds + 1
14    }));
15 }
16
17 // called after the component was created/added to the
18 // browser window
19 componentDidMount() {
20     this.interval = setInterval(() => this.tick(), 1000);
21 }
22
23 // called before the component will be deleted/removed from
24 // the browser window
25 componentWillUnmount() {
26     clearInterval(this.interval);
27 }
28
29 // the actual rendering code
30 // html can be directly embedded into react components
31 // {} blocks will be evaluated when the render method is
32 // called
33 // which will happen any time the props or its internal
34 // states updates
35 render() {
36     return (
37         <div>
38             Seconds: {this.state.seconds}
39         </div>
40     );
41 }
42 }
```

```

39 // mountNode is a reference to a DOM Node
40 // the component will be mounted inside that node
41 ReactDOM.render(<Timer />, mountNode);

```

In conjunction with mobx and TypeScript no classes are used for React components though, but instead Stateless Functional Components ('SFCs'[12]). These SFCs are plain functions, only depending on their passed properties:

```

1 function SomeComponent(props: any) {
2   return <p>{props.first} {props.first}</p>
3 }

```

This component could then be used by:

```

1 <SomeComponent first="Hello" second="World"/>

```

This component systems allows the plugins to define some components and then 'link' them into the program via the hook system, which will be explored later.

MobX

Its main tagline is “Simple, scalable state management”[16]. An introducing overview is shown in Figure 1. Broadly speaking MobX introduces observable objects. Instead of mentioned DOM handling or property passing inside React trees, components can just retrieve their values from the observable objects and will be automatically refreshed if the read values change. This for example makes the implementation of the QuickPan plugin extremely easy, as it can just read the zoom, pan, etc. values of the other plugins and will automatically receive all updates without any further manual observation handling.

mobx-state-tree

“Central in MST (mobx-state-tree) is the concept of a living tree. The tree consists of mutable, but strictly protected objects”[17] This allows the implementation to have one shared state tree which can be used to safely access all data. All nodes inside the state tree are MobX observables. A simple tree with plain MST would look like this:

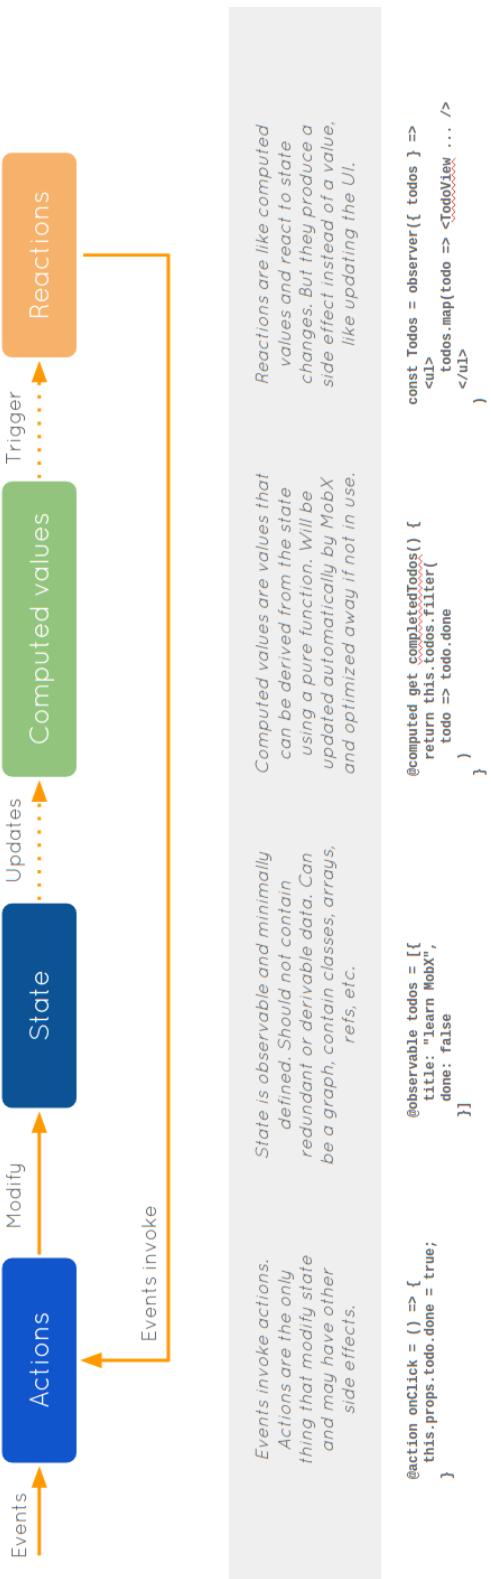

Figure 1: Taken from Weststrate[16]. Actions in the oxrti context are most often initially user actions, which are then calling into plugins to change the state. The state is mostly encapsulated on a plugin basis with usage of the mobx-state-tree library, which also encapsulates most computed values. Reactions are most often the previously discussed React components.

```

1 // define a model type
2 const Todo = types
3   .model("Todo", {
4     // state of every model
5     title: types.string,
6     done: false
7   })
8   .actions(self => ({
9     //methods bounds to the current model instance
10    toggle() {
11      self.done = !self.done
12    }
13  }))
14 // create a tree root, with a property todos
15 const Store = types.model("Store", {
16   todos: types.array(Todo)
17 })

```

This syntax was deemed to convoluted, as it is a lot more complex than standard JavaScript/TypeScript classes, which were introduced by the ES6 version, as shown in the React description above and thus being in conflict with requirement 14.

classy-mst

There is an option to use a more traditional syntax instead though, with the `classy-mst` library, with which the example above becomes[3]:

```

1 const TodoData = types.model({
2   title: types.string,
3   done: false
4
5 });
6
7 class TodoCode extends shim(TodoData) {
8   @action
9   toggle() {
10     this.done = !this.done;
11   }
12 }
13

```

Feature	Chrome	Edge	Firefox (Gecko)	Internet Explorer	Opera	Safari
Basic support	9	(Yes)	4.0 (2.0)	11	12	5.1
WebGL 2	56	No support	51 (51)	No support	43	No support

Feature	Chrome for Android	Edge	Firefox Mobile (Gecko)	IE Mobile	Opera Mobile	Safari Mobile
Basic support	25	(Yes)	4	No support	12	8.1
WebGL 2	?	?	?	?	?	?

Figure 2: WebGL compatibility as from the Mozilla Developer network[22].

```
14 const Todo = mst(TodoCode, TodoData, 'Todo');
```

Weststrate, the original author of MobX initially was sceptic of this syntax[1] as it was changing the semantics of ES6 classes, as classy-mst's methods will be automatically bound to the instance. This boundness is an advantage for this implementation though, as the hook configurations can just refer to `this.someMethod` instead of `this.someMethod.bind(this)`. The `@action` is a decorator, enabling the following method to change the state/properties of the model, as MST prohibits that by default. Reactions/View updates will only happen after the outermost action finished executing.

WebGL

The increasing support of the WebGL stack is the main reason, why it is now feasible to implement a full RTI software stack with plain web technologies, as it “enables web content to use an API based on OpenGL ES 2.0 to perform 3D rendering in an HTML <canvas> in browsers that support it without the use of plug-ins.” [30] OpenGL ES 2.0 likeness means that (most importantly) shaders are supported, allowing the implementation to be split up into multiple shaders with single responsibilities, for details refer to section 5.7. While preserving compatibility and requirement 8 WebGL 2 support is sadly not widespread enough to fully rely on yet (compare Figure 2), as it is currently estimated at 50% of all devices[28]. Potential improvements when WebGL 2 is more widely supported or in conditional plugins are discussed in section 7.3.1. One notable limitation of WebGL is `MAX_TEXTURE_IMAGE_UNITS`, the maximum amount of bound textures inside a single shader, which in most implementations is 16[29], whereas the standard OpenGL implementations are likely to have a limit of 32. This is influencing the BTF file format, as for example in the PTM RGB use case a total of 18 coefficients exist, which now need to be bundled up somehow into maximum 16 textures, if the calculations

should be done inside a single shader. It is also limiting the amount of layers of the Paint plugin, as these also consist of bound textures. Apart from the shaders, which are written in the OpenGL ES Shading Language[27] and the texture loader (section 5.8), no direct WebGL code is necessary nor used anywhere inside the implementation, as the gl-react library is abstracting it neatly for use from the MobX/React environment.

gl-react

“Implement complex effects by composing React components.”[20] is the main use of the gl-react library. A minimal component, adapted from the gl-react-cookbook looks like[20]:

```

1 const shaders = Shaders.create({
2   helloGL: {
3     frag: GLSL`  

4       precision highp float;  

5       varying vec2 uv;  

6       void main() {  

7         gl_FragColor = vec4(uv.x, uv.y, 0.5, 1.0);  

8       }`  

9   }
10 });
11
12 export default class Example extends Component {
13   render() {
14     return (
15       <Surface width={300} height={300}>
16         <Node shader={shaders.helloGL} />
17       </Surface>
18     );
19   }
20 }
```

Which would result in a display like Figure 3. gl-react’s is not a 3D engine, so no objects are to be created or scene graph managed, instead the oxrti implementation can concentrate on solely providing the necessary shaders. gl-react’s default node size is taken from the parent surface size. The surface size will be dependent on the user running the program and his browser windows, which makes it undesirable as details would be lost, if the BTF provided more detail, so the processing Node sizes are usually set to the

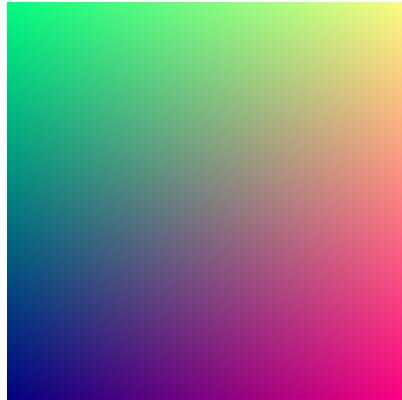

Figure 3: RGBA texture, with R and G according to their respective u or v texture coordinate. From [10].

BTF resolution or higher.

Webpack

Webpack is used to bundle the implementation into single files as it is “a bundler for javascript and friends. Packs many modules into a few bundled assets.” [31] A more detailed discussion on the targets is in section 5.10. Broadly speaking Webpack loads the source code inside the *src* directory according to the loaders defined inside the *webpack.config.js* file, analyses their dependencies and then bundles them together. This makes it possible to have a dependency tree spanning 26184 packages from npm, but still providing a single bundled application file only 1.5 megabyte large (data as of August 23, 2018). It also allows the dynamic plugin structure by bundling the plugins into a dynamic ‘context’ from which single plugins can be loaded at runtime.

Electron

Electron is used to “build cross-platform desktop apps with JavaScript, HTML, and CSS” [7] While theoretically not necessary to fulfill most requirements, as the implementation is compatible with all modern web browsers, providing an additional standalone executable provides some advantages:

- It is possible to add a more traditional menu-based interface, which the browser version could not support.

- Stable development environment, as electron-devtools-installer is used to provide relevant extensions (React devtools, MobX devtools) by default and the hot reloading is reliably tested, which together form a good developer experience (requirement 15)
- It allows to preserve the software in a usable, contained state, not relying on the user also having a compatible web browser in the future.
- It allows future development to more directly access resources of the host machine, e.g. the normal OpenGL stack could be used for calculating the coefficients, as it is less resource constrained compared to the WebGL stack.

MaterialUI

MaterialUI is succinctly described by “React components that implement Google’s Material Design.” [15]. MaterialUI’s component are used throughout the app for styling the components, making the use of custom CSS largely unnecessary apart from minor positioning fixes. For example the Zoom component is defined as:

```

1 // Card, CardContent, Tooltip and Button are all components
2   ↵ provided by MaterialUI.
3 // this refers to the Zoom Plugin's controller which
4 // the content will be automatically refreshed if the referred
5   ↵ values change
6 const Zoom = Component(function ZoomSlider (props) {
7   return <Card style={{ width: '100%' }} >
8     <CardContent>
9       <Tooltip title='Reset'>
10         <Button onClick={this.resetZoom} style={{
11           ↵ marginLeft: '-8px' }}>Zoom</Button>
12       </Tooltip>
13       <Tooltip title={this.scale}>
14         <Slider value={this.scale}
          ↵ onChange={this.onSlider} min={0.01}
          ↵ max={30} />
15       </Tooltip>
16       <Tooltip title='Reset'>
17         <Button onClick={this.resetPan} style={{
18           ↵ marginLeft: '-11px' }}>Pan</Button>

```

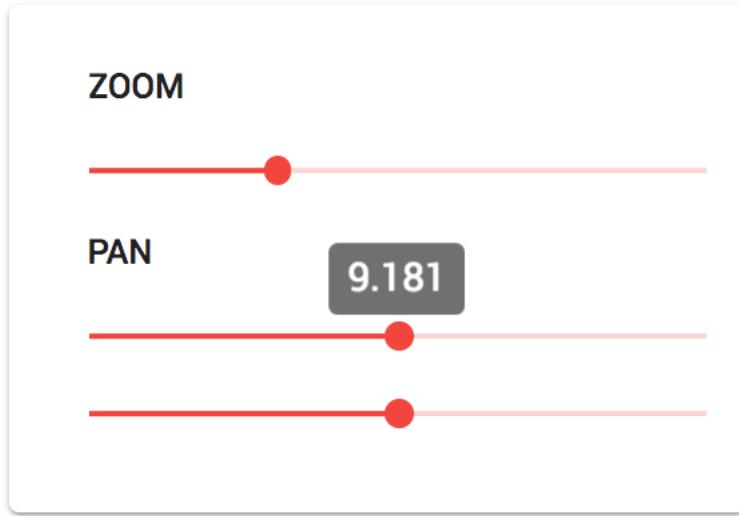

Figure 4: Zoom Component, the user is dragging the zoom slider currently, the mouse pointer is not depicted.

```

15      </Tooltip>
16      <Tooltip title={this.panX}>
17          <Slider value={this.panX}
18              ↵    onChange={this.onSliderX} min={-1 *
19                  ↵    this.scale} max={1 * this.scale} />
20      </Tooltip>
21      <Tooltip title={this.panY}>
22          <Slider value={this.panY}
23              ↵    onChange={this.onSliderY} min={-1 *
24                  ↵    this.scale} max={1 * this.scale} />
25      </Tooltip>
26      </CardContent>
27  </Card>
28 })

```

It would result in a display like Figure 4.

Misc

Further libraries of note are:

electron-webpack[8] is providing the bridging between Webpack and Electron, its config is expanded by the *webpack.renderer.additions.js* and

webpack.renderer.shared.js files.

pngjs[21] is providing in-browser bitwise png manipulation, required in the converter.

jszip[13] is providing in-browser zip file manipulations, which are fundamental for the BTF fileformat.

5.3 Base

The implementation is making a distinction between plugin and non-plugin files. The amount of non-plugin files was aimed for to be as low as possible, as they are inflexible in all output configurations and will have slightly different behaviour while developing in regard to reloads. The files not contained in plugins are the following:

- *AppState.tsx*, the mobx-state-tree root node representing the whole application state in its leafs, detailed in section 5.6.
- *BTFFFile.tsx*, containing the fileformat implementation and utility functions, described in section 5.5.
- *Hook.tsx* and *HookManager.tsx* which provide the whole dynamic interaction system between the different plugins, shown in section 5.4.
- *Loader.tsx*, *electron/index.tsx*, *renderer/index.tsx* and *web/index.tsx*, providing the loading functionality. The Electron application has two entry points, one for the main process, which is *electron/index.tsx* and one for the in-browser content, which is *renderer/index.tsx*. The in-browser one and the plain browser entry point *web/index.tsx* both call the *Loader.tsx* to initialise the state management and mount the root React component, so the user can interact finally. The Loader also handles hot-reloading, it will receive the changed source code from Webpack and update the plugins accordingly.
- *Plugin.tsx* defining the base class for a plugins, further explained in section 5.9.
- *types.d.ts* is providing the custom ambient type declarations for software dependencies, which are not providing TypeScript types on their own. In case new dependencies are added, they are likely to require and addition there.

- *Util.tsx* providing general helper functions, largely related to some math functions for texture coordinate handling.
- *loaders/glsify-loader/index.js* is the custom Webpack loader for *.glsl* files, allowing e.g. the `import zoomShader from './zoom.glsl'` statement and setting up Webpack to contain the shader source in the final bundle.
- *loaders/oxrtidatatem/OxrtiDataTextureLoader.tsx* is providing direct texture loading from in-memory BTF files, discussed in section 5.8.

5.4 Hooks

The hook system allows stable and prioritized interactions between the different plugins. All available hooks are declared inside the *Hook.tsx* file, which offers 3 different types of hooks:

```

1 // Hooks are sorted in descending priority order in their
   ↳ respective `HookManager`
2 export type HookBase = { priority?: number }
3
4 // Generic single component hook, usually used for rendering
   ↳ a dynamic list of components
5 export type ComponentHook<P = PluginComponentType> = HookBase &
   ↳ { component: P }
6
7 // Generic single component hook, usually used for
   ↳ notifications
8 export type FunctionHook<P = (...args: any[]) => any> =
   ↳ HookBase & { func: P }
9
10 // Generic hook config, requiring more work at the consumer
    ↳ side
11 export type ConfigHook<P = any> = HookBase & P
12
13 // union of all hooks to allow for manual hook distinction
14 export type UnknownHook = ComponentHook & FunctionHook &
   ↳ ConfigHook
15
16 // object of named hooks
17 type Hooks<P> = { [key: string]: P }
```

```

18
19 // collection of unknown hooks
20 export type UnknownHooks = Hooks<UnknownHook>
21
22 // hook configuration inside plugins:
23 //   ↳ 1-Hookname->*-LocalName->1-HookConfig
23 export type HookConfig = { [P in keyof HookTypes]: 
24   ↳ Hooks<HookTypes[P]> }
25
25 // all hooknames
26 export type HookName = keyof HookConfig
27
28 // map one hookname to its type
29 export type HookType<P extends HookName> = HookTypes[P]
30
31 // list of hooknames inside hook collection T, having
32 //   ↳ hooktype U
32 type LimitedHooks<T, U> = ({ [P in keyof T]: T[P] extends U ? P
33   ↳ : never })[keyof T]
34
34 // limit hookname parameters to a type conforming subset,
35 //   ↳ e.g. LimitedHook<ComponentHook>
35 export type LimitedHook<P> = LimitedHooks<HookConfig, Hooks<P>>

```

These types are used to first declare single hook types (which will be discussed within the plugins consuming them) and then construct the whole hook configuration tree for all plugins:

```

1 type HookTypes = {
2   ActionBar?: ConfigHook<ActionBar>,
3   AfterPluginLoads?: FunctionHook,
4   AppView?: ComponentHook,
5   ...
6 }

```

A plugin then can link itself into these hooks with its hooks method, for example:

```

1 get hooks () {
2   return {
3     // register things for the ViewerSide hook / add
4     //   ↳ components to the side bar
5     ViewerSide: {

```

```

5      // a plugin can register itself multiple times with
6      // different names and configurations
7      Metadata: {
8          component: BTFFMetadataConciseDisplay,
9          // hooks will be sorted internally in priority order,
10         // highest first
11         priority: -110,
12     },
13     Open: {
14         component: Upload,
15         priority: 100,
16     },
17 }

```

The state manager (section 5.6) collects all hooks and merges them into the respective HookManagers, which are then used to iterate/map over these:

```

1  /** type definitions for the different iterators */
2  export declare type HookIterator<P extends HookName> = (hook:
3      HookType<P>, fullName: string) => boolean | void;
4  export declare type AsyncHookIterator<P extends HookName> =
5      (hook: HookType<P>, fullName: string) => Promise<boolean | void>;
6  export declare type HookMapper<P extends HookName, S> = (hook:
7      HookType<P>, fullName: string) => S;
8  export declare type HookFind<P extends HookName, S> = (hook:
9      HookType<P>, fullName: string) => S;
10 /**
11  * Manage one named hook */
12 export declare class HookManagerCode extends ShimHookManager {
13     /**
14      * Add some hook into the managed stack
15      * @param name in `Plugin&Hookname&Entryname` form
16      * @param priority higher will be treated first with the
17      * iteratotrs
18      */
19     insert(name: string, priority?: number): void;

```

```

14    /** Iterate with iterator over all registered hooks, stop
15     * iteration if the iterator is returning true, name is
16     * redundant as it could be inferred from ourselves, but
17     * allows for easy typesafe calling, AppState is needed
18     * to retrieve the current plugin instance */
19     forEach<P extends HookName>(iterator: HookIterator<P>,
20      name: P, AppState: IAppState): void;
21     /** iterate over all hooks, but wait for asynchronous
22      * hooks to finish before executing the next one */
23     asyncForEach<P extends HookName>(iterator:
24       AsyncHookIterator<P>, name: P, AppState: IAppState):
25       Promise<void>;
26     /** iterate in reverse order */
27     forEachReverse<P extends HookName>(iterator:
28       HookIterator<P>, name: P, AppState: IAppState): void;
29     /** map over all hooks */
30     map<S, P extends HookName>(mapper: HookMapper<P, S>, name:
31       HookName, AppState: IAppState): S[];
32     /** get the concrete hook at index number */
33     pick<P extends HookName>(index: number, name: P, AppState:
34       IAppState): HookType<P>;
35   }

```

5.5 BTF File

The full standalone BTF file format specification can be found inside Appendix A. The implementation in *BTFFile.tsx* is an in-memory implementation of that file with following interface, it is mainly a ‘dumb’ data container.

```

1  export default class BTFFile {
2    /** running id numbers to allow easy cache busts */
3    id: number;
4    /** JSON object of the included oxrti state */
5    oxrtiState: object;
6    /** default data representation */
7    data: Data;
8    /** reference to annotation layers */
9    layers: AnnotationLayer[];
10   /** user visible name */

```

```

11     name: string;
12     /** manifest can come from an unpacked zip, usually typed
13      → as any */
14     constructor(manifest?: BTFFFile);
15     /** canonical zip name for name and id */
16     zipName(): string;
17     /** return true if no data is contained/is dummy object
18      → */
19     isDefault(): boolean;
20     /** export the JSON data of the manifest.json file */
21     generateManifest(): string;
22     /** export user visible shortened metadata */
23     conciseManifest(): string;
24     /**
25      * Generate a unique tex container which the gl-react
26      → loader will cache
27      * @param channel reference to the named channel
28      * @param coefficient reference to the named child
29      → coefficient of channel
30      */
31     texForRender(channel: string, coefficient: string):
32       TexForRender;
33     /**
34      * Generate a tex configuration for a layer
35      * @param id of the layer, must be found in this.layers
36      */
37     annotationTexForRender(id: string): TexForRender;
38     /** aspect ratio of the contained data */
39     aspectRatio(): number;
40     /** package the current data into a zip blob */
41     generateZip(): Promise<Blob>;
42   }
43   /** unpackage a zip blob into a BTFFFile */
44   export declare function fromZip(zipData: Blob | ArrayBuffer):
45     → Promise<BTFFFile>;

```

Notable is the `PreDownload` hook which is called before the `generateZip` function is called, to allow the `ImpExp` plugin and the `Paint` plugin to fill the BTF with their respective data. This hook is called by the `AppState` though, as the `BTFFFile` implementation is fully standalone (apart from the `jszip` dependency), in case other software wishes to re-use the implementation.

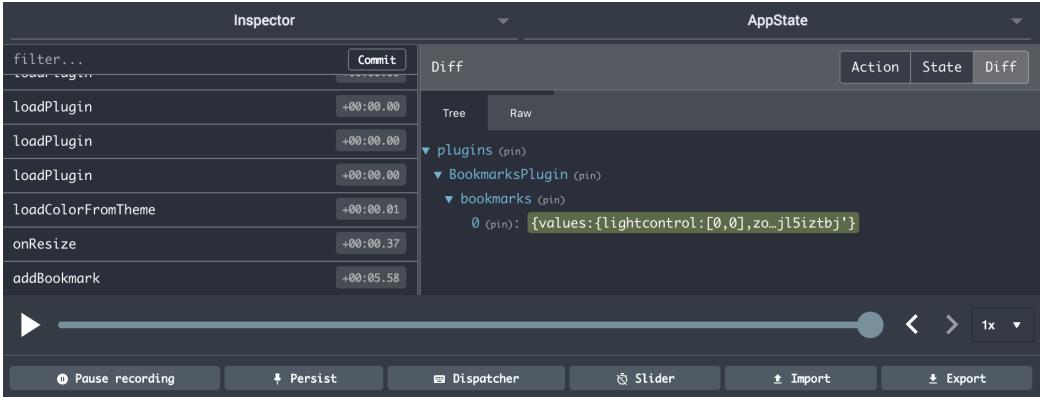

Figure 5: Run MobX at application startup and after one click on ‘Add Bookmark’. The differential of that action is on the right.

5.6 State Management

The *AppState.tsx* file is the root of the applications state tree, but itself only contains limited data:

```

1 // types refering to MST types
2 const AppStateData = types.model({
3   // keep references to loaded plugins
4   plugins: types.late(() => types.optional(types.map(Plugin),
5     => {})),
6   // have a HookManager for each HookName
7   hooks: types.optional(types.map(HookManager), {}),
8   // currently opened BTFCache file, name is the key for the
9   // currentFile: '',
10 })

```

Its main function is to load all plugins and then let them share data between each other via the hook system. The set of to be loaded plugins is defined inside *oxrti.plugins.json*, the plugins defined there will be loaded in order. The state tree after initial plugin load is shown in Figure 6. As only @actions can modify the state, it is easy to follow the changing app state, as shown in Figure 5.

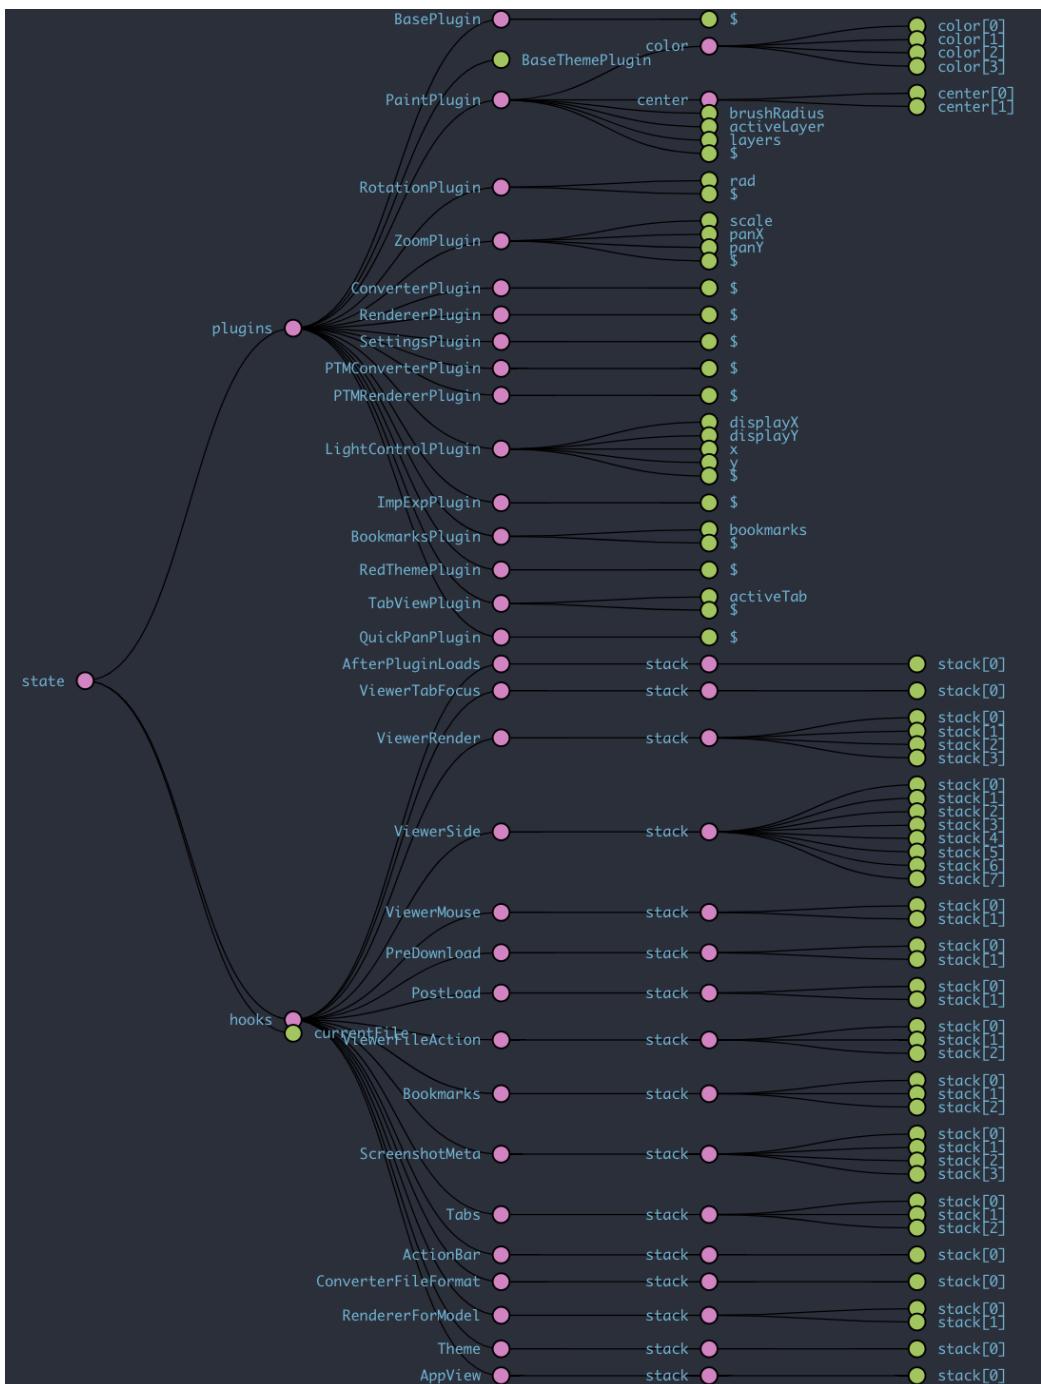

Figure 6: State tree after initial application load. All plugins are initialized and their hooks are registered. Visualized with redux dev tools.[19]

5.7 Renderer Stack

Even though the renderer stack is fully contained in the plugins, its principles span most of them, thus an overview is in order. All WebGL rendering is done through the gl-react library. If a plugin wants to register a node inside the stack, it is using the hook system, e.g. the Rotation plugin:

```
1 // register two nodes inside the rendering stack
2 // higher priority will be run first
3 ViewerRender: {
4     // first center the underlying texture
5     Centerer: {
6         component: CentererComponent,
7         inversePoint: this.undoCurrentCenterer,
8         priority: 11,
9     },
10    // then rotate it
11    Rotation: {
12        component: RotationComponent,
13        inversePoint: this.undoCurrentRotation,
14        priority: 10,
15    },
16}
```

The registered nodes are components again, which will link them into the automated mobx reactions, for example the Centerer node:

```
1 export const CentererComponent = Component(function
2     → CentererNode (props) {
3         // dynamic sizes depending on the loaded btf
4         // if the btf changes, the uniforms will be updated
5         → automatically
6         let [width, height] = this.centererSizes
7         let maxDims = this.maxDims
8         // create one gl-react Node
9         return <Node
10            width={maxDims}
11            height={maxDims}
12            shader={{
```

```
11                // shader from import centerShader from
12                → './centerer.gsls'
13                frag: centerShader,
```

```

13     }
14     // uniforms will be automatically type-converted to
15     // → the appropriate WebGL types
16     uniforms={{
17       // referring to rendering output one step before
18       children: props.children,
19       inputHeight: height,
20       inputWidth: width,
21       maxDim: maxDims,
22     }} />
23   )

```

For the currently delivered default configuration the following nodes are registered:

1. PaintNode
2. CentererNode
3. RotationNode
4. ZoomNode

The Renderer plugin will start by picking the proper base rendering node depending on the channel format of the currently loaded BTF file (btf inside the code):

```

1 props.appState.hookForEach('RendererForModel', (Hook) => {
2   if (Hook.channelModel === btf.data.channelModel) {
3     current = <Hook.node
4       key={btf.id}
5       lightPos={lightControl.lightPos}
6     />
7   }
8 })

```

This initial node will then be wrapped by the registered nodes:

```

1 props.appState.hookForEach('ViewerRender', (Hook) => {
2   current = <Hook.component
3     key={btf.id}
4   >{current}</Hook.component>
5 })

```

5.8 Texture Loader

The bridge between the loaded BTF files and the WebGL contexts needs to be closed with custom code, as gl-react was not supporting the load of PNG textures from memory. An abridged version of the code follows, as it is a good example of the Promise pattern used in some following parts.

```
1  loadTexture(config: TexForRender) {
2      // keep track of the amount of currently loading textures
3      appState.textureIsLoading()
4      // shortcut for the WebGL reference
5      let gl = this.gl
6      // access the raw data buffer from the texture config
7      let data = config.data
8      // create a Promise
9      // it is basically chaining callbacks together
10     // and then asynchronously executing each step
11     let promise =
12         // first create an ImageBitmap object
13         // we need to flipY as the textures are orientated
14         // naturally inside the BTF file
15         // but WebGL is expecting them bottom row first
16         createImageBitmap(data, { imageOrientation: 'flipY' })
17         // the catch step is called if the previous part
18         // failed
19         .catch((reason) => {
20             // some browsers do not like loading a lot of big
21             // textures parrelly
22             // and will garbage collect them in between and
23             // thus fail
24             // as a fallback the limiter function is used to
25             // limit concurrency of that part to 1
26             // this still allow max currency for other
27             // environments
28             return limiter(() => createImageBitmap(data))
29         })
30         // the then part is called when the previous step
31         // succeeded
32         .then(img => {
33             // create and bind a new WebGL texture
34             let texture = gl.createTexture()
```

```

28         gl.bindTexture(gl.TEXTURE_2D, texture)
29     let type: number
30     // map the type from the BTF file to a WebGL
31     // → texture type
32     switch (config.format) {
33         case 'PNG8':
34             type = gl.LUMINANCE
35             break
36         X           // ...
37         case 'PNG32':
38             type = gl.RGBA
39             break
40     }
41     // load the imageBitmap into the texture
42     gl.texImage2D(gl.TEXTURE_2D, 0, type, type,
43                   gl.UNSIGNED_BYTE, img)
44     gl.texParameteri(gl.TEXTURE_2D,
45                      gl.TEXTURE_MIN_FILTER, gl.NEAREST)
46     gl.texParameteri(gl.TEXTURE_2D,
47                      gl.TEXTURE_MAG_FILTER, gl.NEAREST)
48     // finished and return
49     appState.textureLoaded()
50     return { texture, width: img.width, height:
51             img.height }
52   })
53   .catch((reason) => {
54     // a null texture will be empty
55     alert('Texture failed to load' + reason)
56     appState.textureLoaded()
57     return { texture: null, width: config.width,
58             height: config.height }
59   })
60   // the calling code will have its own catch/then logic
61   return promise
62 }

```

5.9 Plugins

All plugins extend the relatively limited abstract plugin class in *Plugin.tsx* and have no preserved state:

```

1  /** General Plugin controller, will be loaded into the MobX
2   → state tree */
3  export declare class PluginController extends PluginShim {
4      /** referential access to app state, will be set by the
5       → plugin loader */
6      appState: IAppState;
7      /** called when the plugin is initially loaded from file
8       → */
9      load(appState: IAppState): void;
10     /** all hooks the plugin is using */
11     readonly hooks: HookConfig;
12     /** get a single typed hook */
13     hook<P extends HookName>(name: P, instance: string):
14      → HookType<P>;
15     /** called before the plugin will be deleted from the
16      → state tree, ususally used for volatile state fixes,
17      → e.g. paint layers */
18     hotUnload(): void;
19     /** called after the plugin was restored in the state
20      → tree */
21     hotReload(): void;
22     /** convenience function to inverse a rendering point
23      → from surface coordinates into texture coordinates */
24     inversePoint(point: Point): Point;
25     /** some components need references to their actual DOM
26      → nodes, these are stored outside the plugins scope to
27      → allow hot-reloads */
28     handleRef(id: string): (ref: any) => void;
29     /** return a stored ref */
30     ref(id: string): any;
31   }

```

The most important function is the `PluginCreator`, which merges the mobx-state-tree model with the classy-mst controller code and provides a wrapper function to create components bound to the containing plugin:

```

1  /**
2   * Create Subplugins
3   * @param Code is the controller
4   * @param Data is the model
5   * @param name must be the same as the folder and filename
6   */

```

```

7  function PluginCreator<S extends ModelProperties, T, U> (Code:
   ↵  new () => U, Data: IModelType<S, T>, name: string) {
8    // create the resulting plugin class
9    let SubPlugin = mst(Code, Data, name)
10   // higher-order-component
11   // inner is basically (props, classes?) => ReactElement
12   // inner this will be bound to the SubPlugin instance
13   type innerType<P, C extends string> = (this: typeof
   ↵  SubPlugin.Type, props: ComponentProps & { children?:
   ↵  ReactNode } & P, classes?: ClassNameMap<C>) =>
   ↵  ReactElement<any>
14   // P are they freely definable properties of the embedded
   ↵  react component
15   // C are the inferred class keys for styling, usually no
   ↵  need to manually pass them
16   function SubComponent<P = {}, C extends string = ''>
   ↵  (inner: innerType<P, C>, styles?:
   ↵  StyleRulesCallback<C>): PluginComponentType<P> {
17     // wrapper function to extract the corresponding
   ↵  plugin from props into plugin argument typedly
18     let innerMost = function (props: any) {
19       let plugin = (props.appState.plugins.get(name)) as
   ↵  typeof SubPlugin.Type
20       // actual rendering function
21       // allow this so all code inside a plugin can just
   ↵  refer to this
22       let innerProps = [props]
23       // append styles
24       if (styles)
25         innerProps.push(props.classes)
26       // call the embedded component
27       return inner.apply(plugin, innerProps)
28     };
29     // set a nice name for the MobX/redux dev tools
30     (innerMost as any).displayName = inner.name
31     // use MobX higher order functions to link into the
   ↵  state tree
32     let func: any = inject('appState')(observer(innerMost))
33     // wrap with material-ui styles if provided
34     if (styles)
35       func = withStyles(styles)(func);

```

```

36     // also name the wrapped function for dev tools
37     func as PluginComponentType<P>).displayName =
38         → `PluginComponent(${inner.name})`
39     return func
40 }
41 // allow easier renaming in the calling module
42 return { Plugin: SubPlugin, Component: SubComponent }
43 }
```

A minimal example would be:

```

1 const BasePluginModel = Plugin.props({
2   greeting: 'In the beginning was the deed!',
3 })
4
5 class BasePluginController extends shim(BasePluginModel,
6   → Plugin) {
7   @action
8   onGreeting (event: any) {
9     this.greeting += '!'
10  }
11
12 // general plugin template code
13 const { Plugin: BasePlugin, Component } =
14   → PluginCreator(BasePluginController, BasePluginModel,
15   → 'BasePlugin')
16 export default BasePlugin
17 // export the type to allow other plugins to retrieve this
18   → plugin
19 export type IBasePlugin = typeof BasePlugin.Type
20
21 // CSS styles, classnames will be mangled, so styles is
22   → passed to the component
23 const styles = (theme: Theme) => createStyles({
24   hello: {
25     color: 'red',
26   },
27 })
28
29 // props are standard react props, classes contains the
30   → mangled names
```

```

26 const HelloWorld = Component(function HelloWorld (props,
27   ↵ classes) {
28     return <p className={classes.hello}
29       ↵ onClick={this.onGreeting}>{this.greeting}</p>
30   }, styles)

```

The rest of the plugins are presented on a higher conceptual level, as their internal APIs are most times used only by themselves. Their hooks will be discussed though.

5.9.1 Base Plugin

The base plugin is containing no further internal logic, but only is providing some shared display components. These could theoretically have been implemented outside of any plugin, but putting them into the Base plugin simplifies the distinction between components bound to plugins and unbound plugins, by having no unbound plugins at all. It also simplifies the code loading, as just the Base plugin can be (re-)loaded like all other plugins. The provided components are:

- JSONDisplay, showing a JSON object in a prettified form, used for displaying different metadata objects
- BTFFMetadataDisplay, showing the currently loaded BTF's data
- RenderHooks, to render all components attached to a hook
- SafeGLInspector, wrapping the secondary WebGL surfaces and disabling theme, if WebGL debug tools are used, which can handle only one surface.
- Tooltip, wrapping the material-ui tooltip component to fix styling errors

5.9.2 BaseTheme, RedTheme and BlueTheme Plugin

The BaseTheme plugin is having two essential properties:

```

1  /** app wide theme definitions */
2  themeBase: ThemeOptions = {
3    palette: {
4      },
5    overrides: {

```

```

6     MuiTooltip: {
7         tooltip: {
8             fontSize: 16,
9         },
10        tooltipPlacementBottom: {
11            marginTop: 5,
12        },
13        tooltipPlacementTop: {
14            marginBottom: 5,
15        },
16    },
17 },
18 }
19
20 /** per theme plugin overridable definitions */
21 themeExtension: ThemeOptions = {}

```

Concrete themes (at the moment RedTheme and BlueTheme plugins) extend this BaseTheme and then set their `themeExtension` according to their modifications. To pick a theme to be used the `ThemeConfig` hook exists:

```

1 type ThemeConfig = {
2     controller: { theme: Theme },
3 }

```

Concrete themes register with:

```

1 get hooks (): HookConfig {
2     return {
3         Theme: {
4             Red: {
5                 priority: 100,
6                 controller: this,
7             },
8         },
9     }
10 }

```

If multiple plugins are registering themes, the `appState` will pick the theme with the highest priority to apply to the app.

5.9.3 TabView Plugin

The TabView plugin is providing the full app experience and is targeted at the Electron output and the online hosted version. As a tabbed container will occasionally delete the content of non-active tabs, some hooks are needed to ensure graceful behaviour of all displayed tabs:

```
1 // register a new tab
2 type Tab = {
3     // component to be the base of the tab
4     content: PluginComponentType
5     tab: TabProps,
6     padding?: number,
7     // async functions to allow customisation before/after
8     // tabs change
9     beforeFocusGain?: () => Promise<void>,
10    afterFocusGain?: () => Promise<void>,
11    beforeFocusLose?: () => Promise<void>,
12    afterFocusLose?: () => Promise<void>,
13 }
14
15 // action buttons on the top rights
16 type ActionBar = {
17     onClick: () => void,
18     title: string,
19     enabled: () => boolean,
20     tooltip?: string,
21 }
22
23 // notifications if the tab changes for sub-components which
24 // are not being a tab themselves
25 type ViewerTabFocus = {
26     beforeGain?: () => void,
27     beforeLose?: () => void,
28 }
```

This view is depicted in Figure 7.

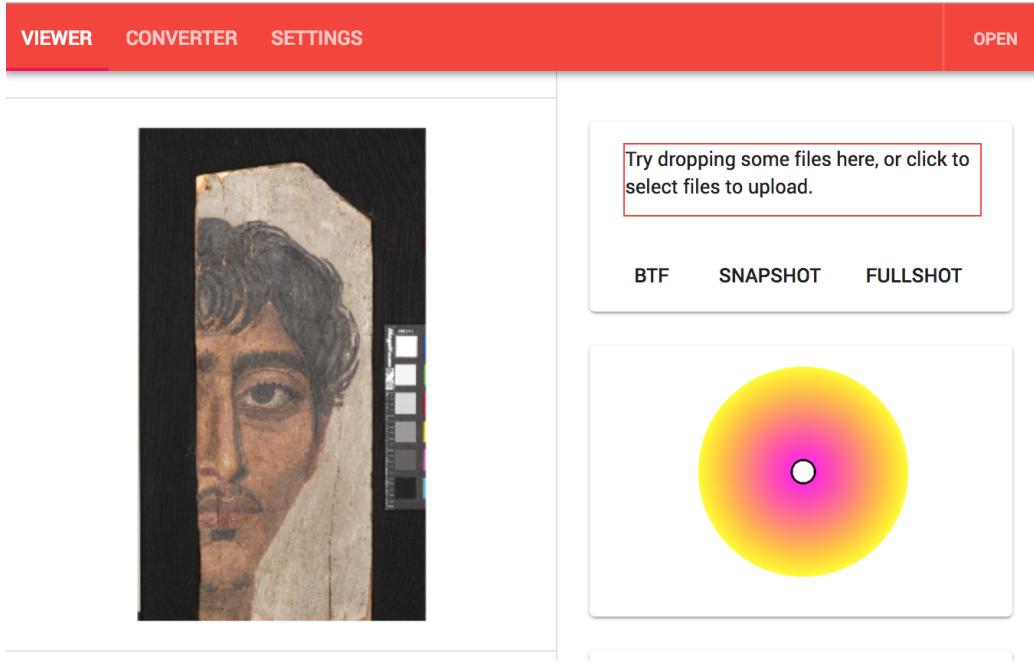

Figure 7: Viewer with loaded TabView and RedTheme plugins. Tabbar on top, with action buttons on top right.

5.9.4 SingleView Plugin

The SingleView plugin is aimed to provide a contained viewer experience, e.g. on a museum's website, it is just displaying the tab with the highest priority, see Figure 8.

5.9.5 Converter Plugin

The Converter plugin consists of multiple parts:

- The converter user interface, as shown in Figure 9.
- BMPWriter and PNGWriter, both extending Writer to write the converted textures. The BMPWriter is customised as no current package is offering the required functionality. The PNGWriter is wrapping pngjs.
- An abstract base converter strategy, to be extended by plugins providing a concrete converter with the following interface:

```

1  export default abstract class ConverterStrategy {
2      /** raw file buffer */

```

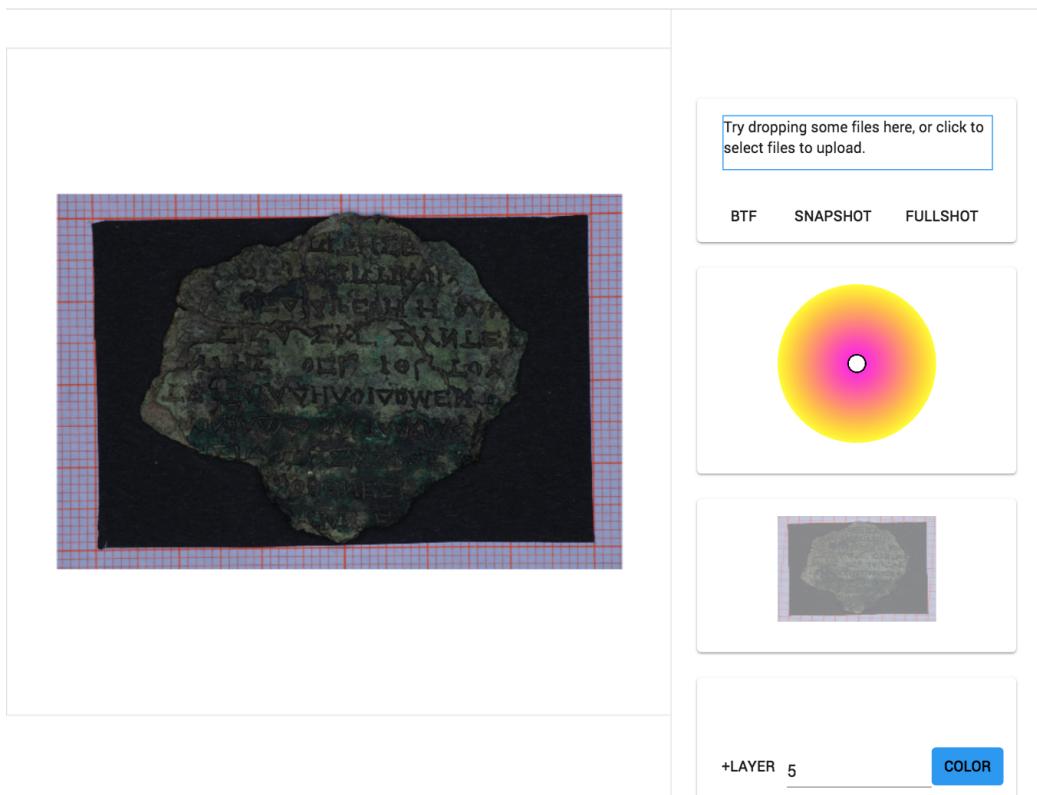

Figure 8: Viewer with loaded SingleView and BlueTheme plugins. Only changes to Figure 7 are two lines in *oxrti.plugins.json*.

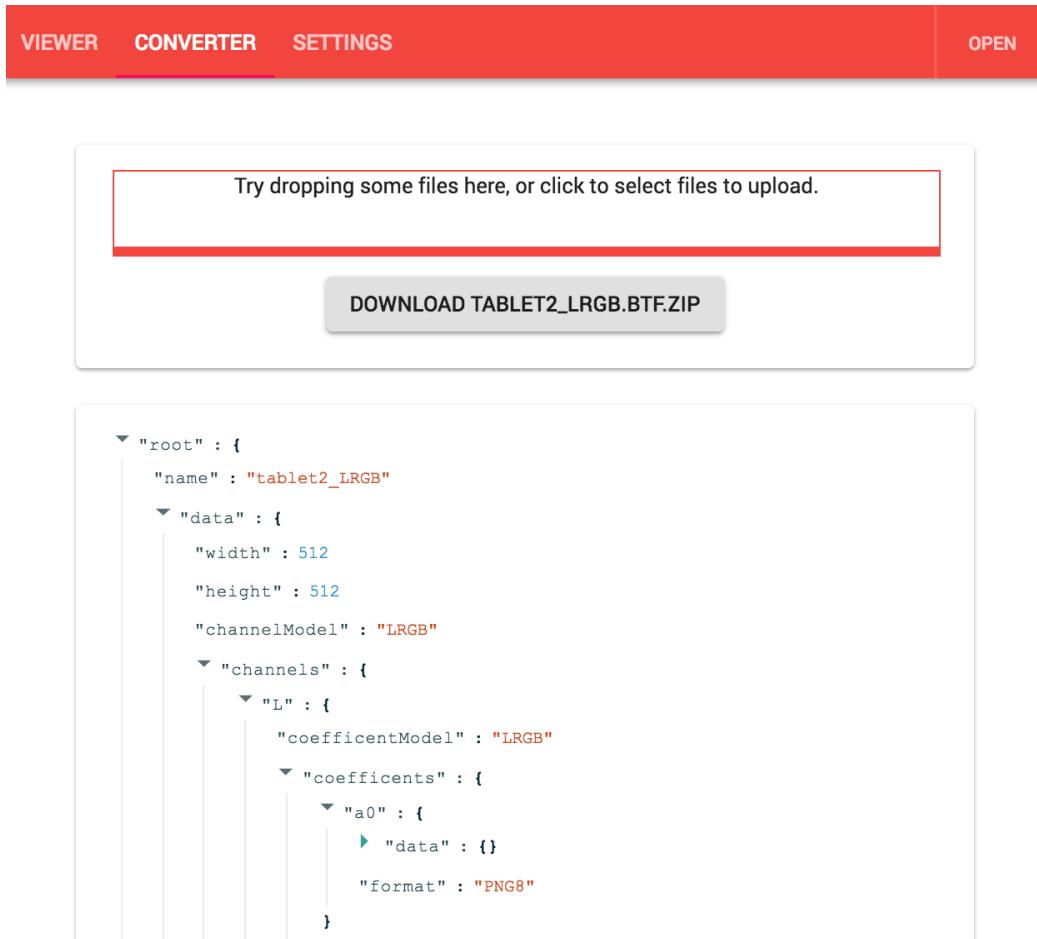

Figure 9: Converter user interface, with display of the extract manifest.

```

3   fileBuffer: ArrayBuffer;
4   /** wrapped file buffer */
5   inputBuffer: Buffer;
6   /** UI delegate for status updates */
7   ui: IConverterUI;
8   /** pixelData buffer, pointing into fileBuffer+metadata
9    *  ↳ length */
10  pixelData: Buffer;
11  /** extracted width and height */
12  width: number;
13  height: number;
14  /** concrete BTF output */
15  output: BTFFile;
16  /** freeform format depending JSON object, e.g. biases
17   *  ↳ for PTMs */
18  formatMetadata: object;
19  /** current channelModel as defined in the BTF
20   *  ↳ specification */
21  channelModel: ChannelModel;
22  /** total pixel count */
23  readonly pixels: number;
24  /** started from the converter ui */
25  constructor(content: ArrayBuffer, ui: IConverterUI);
26  /** pointer into the raw file buffer */
27  currentIndex: number;
28  /** read metadata till newline */
29  readTillNewLine(): string;
30  /** read one item, usually byte */
31  readOne(): number;
32  /** prepare pixeldata buffer */
33  preparePixelData(): Promise<void>;
34  /** run the actual conversion */
35  process(): Promise<BTFFile>;
36  /** only these need to implemented by concrete converters
37   *  ↳ */
38  /** read the metadata block */
39  abstract parseMetadata(): Promise<void>;
40  /** read the pixel block */
41  abstract readPixels(): Promise<void>;
42  /** read potential suffix after pixel block */
43  abstract readSuffix(): Promise<void>;

```

```

40     /** bundle the read pixels into channels according to the
41      ↵ channelModel */
42     abstract bundleChannels(): Promise<Channels>;
43   }

```

If a plugin wants to register a concrete converter it would use following hook:

```

1 ConverterFileFormat: {
2   PTM: {
3     fileEndings: ['.ptm'],
4     // refering to the class extending the base strategy
5     strategy: PTMConverterStrategy,
6   },
7 }

```

5.9.6 PTMConverter Plugin

The PTM Converter plugin is converting `.ptm` files, as they are described in section 2.2. Currently the RGB and LRGB lightning models are supported. Their main interesting code is the pixel data reader:

```

1 async readPixelsLRGB () {
2   // allocate output buffers for [a_0', 'a_1', 'a_2',
3   ↵ 'a_3', 'a_4', 'a_5', 'R', 'G', 'B']
4   this.coeffData = this.coeffNames.map(e =>
5     Buffer.alloc(this.pixels))
6   // this.pixelData contains pixels * [a_0, a_1, a_2, a_3,
7   ↵ a_4, a_5] and then pixels * [R, G, B]
8   for (let y = 0; y < this.height; ++y)
9     for (let x = 0; x < this.width; ++x) {
10       // iterate over pixels
11       let originalIndex = ((y * this.width) + x)
12       // flip the Y index, as PTM is bottom-row first,
13       ↵ whereas BTF is top-row first
14       let targetIndex = ((this.height - 1 - y) *
15         ↵ this.width) + x
16       // read from the coefficient block
17       for (let i = 0; i <= 5; i++)
18         this.coeffData[i][targetIndex] =
19           this.pixelData[originalIndex * 6 + i]

```

```

14     // read from RGB block by skipping over the
15     // coefficient block and then iterating colors
16     for (let i = 0; i <= 2; i++) {
17         this.coeffData[i + 6][targetIndex] =
18             this.pixelData[this.pixels * 6 +
19             originalIndex * 3 + i]
20     // update the progress bar
21     if (originalIndex % (this.pixels / 100) === 0) {
22         await this.ui.setProgress(originalIndex /
23             this.pixels * 100 + 1)
24     }
25 }
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
// read from RGB block by skipping over the
// coefficient block and then iterating colors
for (let i = 0; i <= 2; i++) {
    this.coeffData[i + 6][targetIndex] =
        this.pixelData[this.pixels * 6 +
        originalIndex * 3 + i]
// update the progress bar
if (originalIndex % (this.pixels / 100) === 0) {
    await this.ui.setProgress(originalIndex /
        this.pixels * 100 + 1)
}
}

async readPixelsRGB () {
    // allocate output buffers for ['R0R1R2', 'R3R4R5',
    // 'G0G1G2', 'G3G4G5', 'B0B1B2', 'B3B4B5']
    this.coeffData = this.coeffNames.map(e =>
        Buffer.alloc(this.pixels * 3))
    // this.pixelData contains a block of pixels * [a_0,
    // a_1, a_2, a_3, a_4, a_5] for each color
    for (let y = 0; y < this.height; ++y) {
        for (let x = 0; x < this.width; ++x) {
            for (let color = 0; color <= 2; color++) {
                // iterate over pixels and colors
                let inputIndex = (((y * this.width) + x) +
                    this.pixels * color) * 6
                // flip the Y index, as PTM is bottom-row
                // first, whereas BTF is top-row first
                let targetIndex = (((this.height - 1 - y) *
                    this.width) + x) * 3
                // iterate over the coefficients for the given
                // pixel/inputIndex */
                for (let i = 0; i <= 5; i++) {
                    let bucket = color * 2 + Math.floor(i / 3)
                    this.coeffData[bucket][targetIndex + (i %
                        3)] = this.pixelData[inputIndex + i]
                }
            }
        }
    }
    // update the progress bar
}

```

```

43         if (y % (this.height / 100) === 0) {
44             await this.ui.setProgress(y / this.height * 100 +
45             ↪   1)
46         }
47     }

```

5.9.7 Renderer Plugin

The Renderer plugin is providing the main user interface, which is split into two parts (compare Figure 7), on the left the rendered object and on the right further controls, as such it is using a comprehensive set of hooks:

```

1 // specific channelModel renderers can register their base
2   ↪   node
3 type BaseNodeConfig = {
4     channelModel: ChannelModel,
5     node: PluginComponentType<BaseNodeProps>,
6   }
7
8 // hook for a node in the renderer stack
9 type RendererNode = {
10   component: PluginComponentType,
11   // if the node is transforming the texture coordinates,
12   // and inverse method needs to be provided
13   inversePoint?: (point: Point) => Point,
14 }
15
16 // hook for listening to mouse event inside the main renderer
17 type MouseConfig = {
18   listener: MouseListener,
19   mouseLeft?: () => void,
20 }
21
22 // hook for adding file actions/buttons below the upload
23   ↪   field
24 type ViewerFileAction = {
25   tooltip: string,
26   text: string,
27   action: () => Promise<void>,

```

```

25 }
26
27 // hook for adding information to the metadata file when
28 // shots are exported
28 type ScreenshotMeta = {
29   key: string,
30   fullshot?: () => (string | number)[] | string | number,
31   snapshot?: () => (string | number)[] | string | number,
32 }
33
34 // components to be rendered inside the drawer
35 type ViewerSide = ComponentHook
36
37 // notifications, that a btf file will be exported and
38 // plugins should update their respective data inside the
39 // current in-memory version
40 type PreDownload = FunctionHook
41
42 // notification that a btf file was loaded, plugins can
43 // import extra data
44 type PostLoad = FunctionHook

```

The actual object rendering is done by the stack as described in section 5.7, the Renderer plugin is only providing a dynamically resized and centered surface for the stack to be drawn in. The surface is always kept square, even if the loaded BTF is not, to streamline and simplify texture coordinate handling.

5.9.8 PTMRenderer Plugin

The PTMRenderer Plugin is rendering the RGB and LRGB channel models. Here only the RGB is covered, as the principles for LRGB are the same. Most channel renderers will be split in two parts, one node for the rendering stack:

```

1 const coeffs = ['a0a1a2', 'a3a4a5']
2 // return a texture configuration array for the given
2 // coefficient
3 function mapper (btf: BTFFile, name: string) {
4   return coeffs.map(c => {
5     return btf.texForRender(name, c)

```

```

6         })
7     }
8
9 // render a RGB object
10 const PTMRGB = Component<BaseNodeProps>(function PTMRGB (props)
11   ↪  {
12     let btf = props.appState.btf()
13     return <Node
14       // from ./ptmrgb.gsls
15       shader={shaders.ptmrgb}
16       // adaptive sizing if wanted
17       width={props.width || btf.data.width}
18       height={props.height || btf.data.height}
19       uniforms={{
20         // usually coming from the lightcontrol plugin, is
21         ↪  [x:number, y:number, z:number]
22         lightPosition: props.lightPos,
23         // texture arrays
24         texR: mapper(btf, 'R'),
25         texG: mapper(btf, 'G'),
26         texB: mapper(btf, 'B'),
27         // retrieve the untyped formatExtra
28         biases: (btf.data.formatExtra as
29           ↪  PTMFormatMetadata).biases,
30         scales: (btf.data.formatExtra as
31           ↪  PTMFormatMetadata).scales,
32       }} />
33   }
34 )

```

And one shader, implementing the lightning model described in section 2.2.

```

precision highp float;
varying vec2 uv;
// higher and lower coefficents per color
uniform sampler2D texR[2];
uniform sampler2D texG[2];
uniform sampler2D texB[2];
uniform float biases[6];
uniform float scales[6];
uniform vec3 lightPosition;

float channelLum(sampler2D[2] coeffsTexs, vec3 toLight) {

```

```

// would be unrolled by the GLSL compiler anyway
float a0 = texture2D(coeffsTexs[0], uv).x;
float a1 = texture2D(coeffsTexs[0], uv).y;
float a2 = texture2D(coeffsTexs[0], uv).z;
float a3 = texture2D(coeffsTexs[1], uv).x;
float a4 = texture2D(coeffsTexs[1], uv).y;
float a5 = texture2D(coeffsTexs[1], uv).z;

a0 = (a0 * 255.0 - biases[0]) * scales[0];
a1 = (a1 * 255.0 - biases[1]) * scales[1];
a2 = (a2 * 255.0 - biases[2]) * scales[2];
a3 = (a3 * 255.0 - biases[3]) * scales[3];
a4 = (a4 * 255.0 - biases[4]) * scales[4];
a5 = (a5 * 255.0 - biases[5]) * scales[5];

float Lu = toLight.x;
float Lv = toLight.y;

float lum =
    a0 * Lu * Lu +
    a1 * Lv * Lv +
    a2 * Lu * Lv +
    a3 * Lu +
    a4 * Lv +
    a5
)/255.0;
return lum;
}

void main() {
// spotlight behaviour at the moment
vec3 pointPos = vec3(0,0,0);
vec3 toLight = normalize(lightPosition - pointPos);

float R = channelLum(texR, toLight);
float G = channelLum(texG, toLight);
float B = channelLum(texB, toLight);

gl_FragColor = vec4(R,G,B,1.0);
}

```

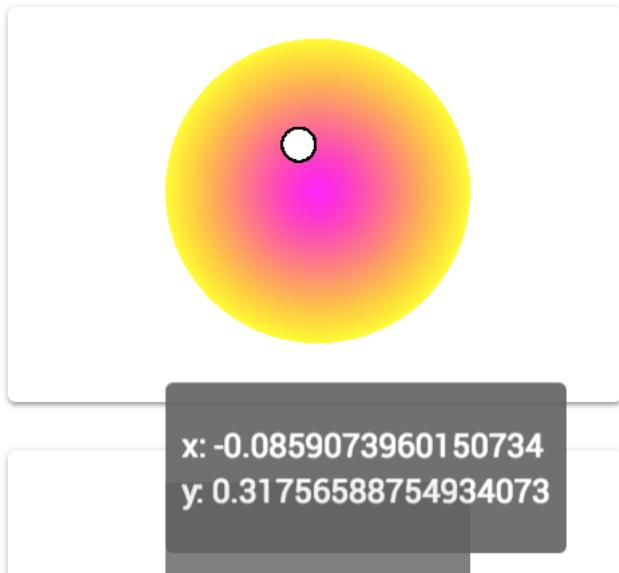

Figure 10: The user can drag around on the imaginary dome and change the lightning position.

5.9.9 LightControl Plugin

The LightControl plugin is providing a visual way to control the position of the light source. The user interface is shown in Figure 10. The linear xy coordinates are transformed into hemispherical coordinates, which are then passed onto the current Base node from the Renderer plugin.

5.9.10 Rotation Plugin

The Rotation plugin allows the rotation of the viewed object (and other lower rendering nodes). It does so by first centering the object inside a large square node of the maximal spanning length when rotated ($width * Math.cos(Math.PI/4) + height * Math.sin(Math.PI/4)$), so no part will be cut off for the rendering layers on top, and then applying a simple rotation matrix on the texture coordinates on the next node. An applied rotation is visible in Figure 11. Even though the whole renderer is rotated, the use of rotation slider will dynamically adapt the pan values to keep the previous center centered.

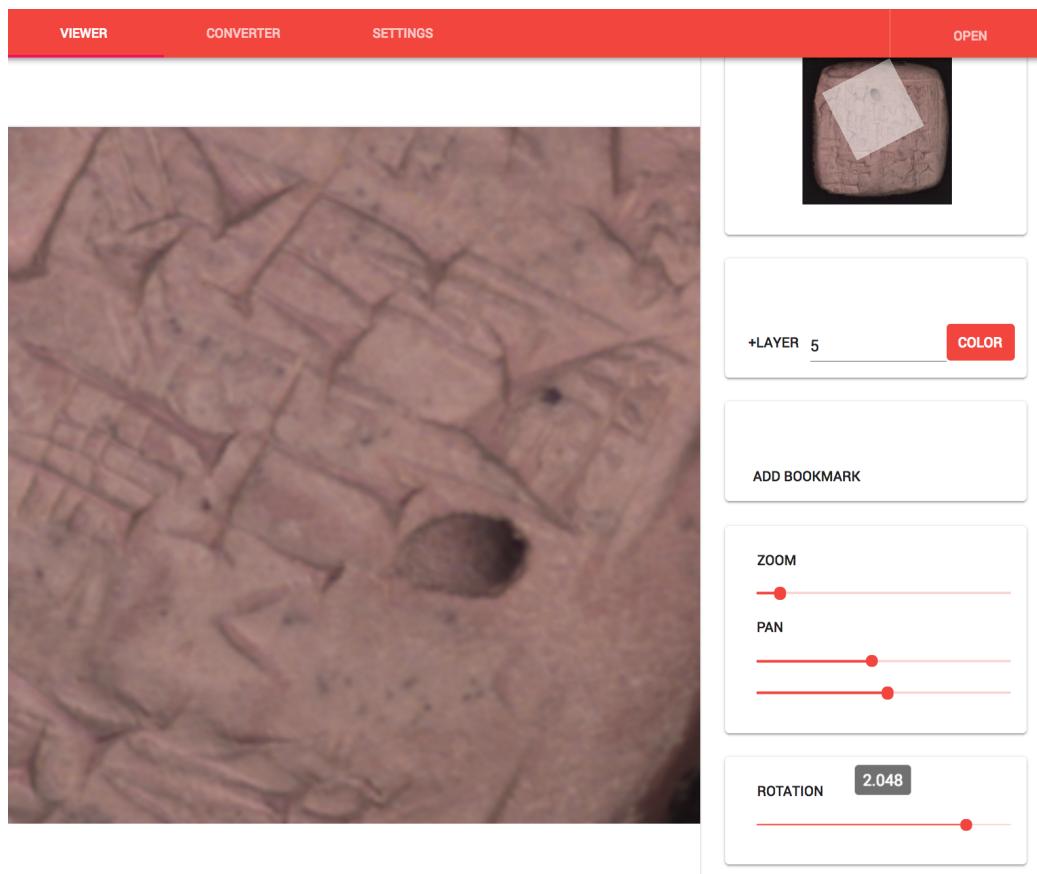

Figure 11: Rotated object. Note that the QuickPan views is also rotated.

Figure 12

5.9.11 Zoom Plugin

The Zoom plugin is providing zoom and pan functionality (pan would not be necessary without zoom), an example is Figure 12.

Conclusion

This is the specification of the BTF fileformat, as of version 1.0 on August 23, 2018. It was developed co-supervisor Stefano Gogioso, with input from and extension by the author of the enclosing thesis in relation to the oxrti viewer.

A BTF File Format

This section describes the BTF file format. The aim of this file format is to provide a generic container for BTF data to be specified using a variety of common formats. Files shall have the `.btf.zip` extension.

A.1 File Structure

A BTF file is a ZIP file containing the following:

- A **manifest** file in JSON format, named `manifest.json`. The manifest contains all information about the BRDF/BSDF model being used, including the names for the available **channels** (e.g. R, G and B for the 3-channel RGB), the names of the necessary **coefficients** (e.g. bi-quadratic coefficients) and the **image file format** for each channel.
- A single folder named **data**, with sub-folders having names in 1-to-1 correspondence with the channels specified in the manifest.
- Within each channel folder, greyscale image files having names in 1-to-1 correspondence with the coefficients specified in the manifest, each in the image file format specified in the manifest for the corresponding channel. For example, if one is working with RGB format (3-channels named R, G and B) in the PTM model (five coefficients `a2`, `b2`, `a1`, `b1` and `c`, specifying a bi-quadratic) using 16-bit greyscale bitmaps, the file `/data/B/a2.bmp` is the texture encoding the `a2` coefficient for the blue channel of each point in texture space.
- The datafiles are all in reversed scanline order (meaning from bottom to top), to keep aligned with the original PTM format and allow easier loading into WebGL.

In case of usage with the oxrti viewer, following files can be present in addition to those mentioned above:

A.2 Manifest

The manifest for the BTF file format is a JSON file with root dictionary. The `root` element has two mandatory child elements: one named `data`, and one named `name` with the option of additional child elements (with different names) left open to future extensions of the format.

- The `name` element is a string with a name of the contained object.
- The `data` element has for entries, named `width`, `height`, `channels` and `channel-model`. The `width` and `height` attributes have values in the positive integers describing the dimensions of the BTDF. The `channel-model` attribute has value a non-empty alphanumeric string uniquely identifying the BRDF/BSDF colour model used by the BTF file (see Options section below). The `channels` element has an arbitrary amount of named `channel` entries, according to the `channel-model`.
- Additionally the `data` element has one untyped entry named `formatExtra`, where format implementation specific data can be stored.
- Each `channel` has an `coefficients` child consisting of an arbitrary number of `coefficient` entries, as well as one `coefficient-model` attribute. The `coefficient-model` attribute has value a non-empty alphanumeric string uniquely identifying the BRDF/BSDF approximation model used by the BTF file (see Options section below).
- Each `coefficient` element has one attribute: `format`. The `format` attribute has value a non-empty alphanumeric string uniquely identifying the image file format used to store the channel values (see Options section below).

A.3 Textures

Each image file `/data/CHAN/COEFF.EXT` has the same dimensions specified by the `width` and `height` attributes of the `data` element in the manifest, and is encoded in the greyscale image file format specified by the `format` attribute of the unique `coefficient` element with attribute `name` taking the value `COEFF` (the extension `.EXT` is ignored). The colour value of a pixel (u, v) in the image is the value for coefficient `COEFF` of channel `CHAN` in the BRDF/BSDF for point (u, v) , according to the model jointly specified by the values of the attribute `model` for element `channels` (colour model) and the attribute `model` for element `coefficients` (approximation model).

A.4 Options

At present, the following values are defined for attribute `channel-model` of element `channels`.

- `RGB`: the 3-channel RGB colour model, with channels named `R`, `G` and `B`. This colour model is currently under implementation.
- `LRGB`: the 4-channel LRGB colour model, with channels named `L`, `R`, `G` and `B`. This colour model is currently under implementation.
- `SPECTRAL`: the spectral radiance model, with an arbitrary non-zero number of channels named either all by wavelength (format `---nm`, with `---` an arbitrary non-zero number) or all by frequency format `---Hz`, with `---` an arbitrary non-zero number. This colour model is planned for future implementation.

At present, the following values are defined for attribute `model` of element `coefficients`, where the ending character `*` is to be replaced by an arbitrary number greater than or equal to 1.

- `flat`: flat approximation model (no dependence on light position). This approximation model is currently under implementation.
- `RTIpoly*`: order-* polynomial approximation model for RTI (single view-point BRDF). This approximation model is currently under implementation.
- `RTIharmonic*`: order-* hemispherical harmonic approximation model for RTI (single view-point BRDF). This approximation model is currently under implementation.
- `BRDFpoly*`: order-* polynomial approximation model for BRDFs. This approximation model is planned for future implementation.
- `BRDFharmonic*`: order-* hemispherical harmonic approximation model for BRDFs. This approximation model is planned for future implementation.
- `BSDFpoly*`: order-* polynomial approximation model for BSDFs. This approximation model is planned for future implementation.
- `BSDFharmonic*`: order-* spherical harmonic approximation model for BSDFs. This approximation model is planned for future implementation.

At present, the following values are defined for attribute `format` of elements tagged `coefficient`, where the ending character * is the bit-depth, to be replaced by an allowed positive multiple of 8.

- `BMP*`: greyscale BMP file format with the specified bit-depth (8, 16, 24 or 32). Support for this format is currently under implementation.
- `PNG*`: PNG file format encoding the specified bit-depth (8, 16, 24, 32, 48 or 64). Support for this format is currently under implementation. Different PNG colour options are used to support different bit-depths:
 - `Grayscale` with 8-bit/channel to encode 8-bit bit-depth.
 - `Grayscale` with 16-bit/channel to encode 16-bit bit-depth.
 - `Truecolor` with 8-bit/channel to encode 24-bit bit-depth.
 - `Truecolor and alpha` with 8-bit/channel to encode 32-bit bit-depth.
 - `Truecolor` with 16-bit/channel to encode 48-bit bit-depth.
 - `Truecolor and alpha` with 16-bit/channel to encode 64-bit bit-depth.
